

Fix report: /consultation funnel and site-wide mobile pass

Evolut Ecommerce Solutions - Next.js 16 / React 19 / Tailwind v4

Branch: main • Prepared 10 September 2026

This report documents every defect fixed in this engagement, with the symptom, the verified root cause, the evidence used to confirm it, and the change made. Where a problem was diagnosed but cannot be fixed from the codebase, it is listed under Outstanding rather than presented as done.

A note on verification: every layout and typography claim below was measured in a real browser (computed styles and bounding boxes), not judged by eye. Screenshots were not available in this environment, so numbers are quoted instead.

Summary

#	Issue	Severity	Status
1	Booking form rejected valid submissions with an unusable error	Blocker	Fixed
2	Lead data reached no database	Blocker	Diagnosed - needs client action
3	Cal.com calendar never opened after submit	Blocker	Fixed + hardened
4	Intro video showed a black rectangle until play	High	Fixed
5	Every border-colour utility silently dead site-wide	High (latent)	Diagnosed + worked around
6	Every line-height / letter-spacing utility dead on headings	High (latent)	Fixed
7	Site-wide mobile type and spacing far too large	High	Fixed
8	Countdown leaked DOM nodes in a backgrounded tab	Medium	Fixed
9	Assorted mobile layout defects on the funnel	Medium	Fixed
10	Content and data-integrity corrections	Medium	Fixed

1. Booking form rejected valid submissions

SYMPTOM

Submitting the multi-step booking form returned the message “**Validation failed**” with no indication of which field was wrong. The lead was lost at the final step of the funnel.

ROOT CAUSE

The funnel posted to `/api/contact`, whose Zod schema is written for the general contact page. That schema requires a free-text **message** field of at least 10 characters, which the funnel has no equivalent of, and it has no concept of the qualifier's step answers. Compounding it, the API was already returning a per-field **issues** array and the form was discarding it, rendering only the generic banner. The failure was therefore undiagnosable from the UI.

FIX

Gave the funnel its own endpoint, **POST /api/consultation**, validating a discriminated union of the two shapes it actually submits (onboarding: name + email; qualifier: contact details plus budget, authority, need and timing). Both forms now render the specific message inline under the offending input.

```
fieldErrors: ["Please enter your name"] // verified live in-browser
```

TWO TRAPS CLOSED IN THE PROCESS

- a. The qualifier's option labels now live once in **site-config.ts** and are imported by both the form and the route, so the server can no longer reject a value the form is capable of producing.
- b. **budget** is validated as a plain trimmed string rather than a strict enum. Those display strings contain en dashes, and pinning a server to byte-exact display copy is precisely how a form starts rejecting its own valid output the moment anything re-encodes it.

FILES

src/app/api/consultation/route.ts (new), consultation-form.tsx, consultation-onboarding-modal.tsx, src/lib/site-config.ts, src/lib/request-guard.ts (new)

2. Lead data reached no database

SYMPTOM

Form submissions returned success but nothing appeared in Supabase; the API reported **stored: false**.

ROOT CAUSE

Not a code fault. The configured Supabase project hostname does not resolve in DNS. Probing three hosts from the same server process isolated it conclusively:

```
szzbvbdzqrsrcceijjlm.supabase.co -> getaddrinfo ENOTFOUND
supabase.com                      -> HTTP 404 (reachable)
api.resend.com                    -> HTTP 401 (reachable)
```

READING

Outbound networking is healthy - real email was sent through Resend during testing. Only that one project host fails to resolve, which means the project reference is wrong, or the project was deleted or never finished provisioning.

WORK COMPLETED AGAINST IT

The storage layer is written and waiting. A new table **consultation_leads** (migration 0002) records each lead with the qualifier answers as real columns plus a jsonb copy of the human labels, so a future extra step needs no migration. Each lead is written twice on purpose: once to that structured table, and once mirrored into **contact_submissions** so it appears in the existing /admin inbox with its status workflow, notes and CSV export, with no admin rework. Either write succeeding is enough.

REQUIRED FROM THE CLIENT

Correct NEXT_PUBLIC_SUPABASE_URL, then run migrations 0001 and 0002 in the Supabase SQL editor. No code change is needed once the URL resolves.

3. Cal.com calendar never opened after submit

SYMPTOM

After qualifying, the success screen appeared but the booking calendar area stayed blank, then later showed a Cal.com 404 page inside the frame.

ROOT CAUSE - FIRST INSTANCE

NEXT_PUBLIC_CAL_LINK was unset, so the code fell back to a placeholder slug. Cal.com does **not** serve a 404 page for a username that does not exist - it closes the connection outright. The iframe therefore rendered as a silently blank rectangle with nothing in the console to explain it.

ROOT CAUSE - SECOND INSTANCE

Once set, the variable contained the *whole booking URL* rather than the slug, so the value was concatenated onto the base and produced **https://cal.com/https://cal.com/user/event**, which Cal.com serves as its own styled 404 inside the frame.

EVIDENCE

Verified by request, which also confirmed the embed approach itself was sound:

```
https://cal.com/<valid>?embed=true&layout=month_view -> HTTP 200, 522 KB  
https://cal.com/<placeholder> -> connection closed unexpectedly
```

FIX

Added a normaliser that accepts any shape the value is given - full URL, protocol-less, with or without a trailing slash or query string - and reduces it to the bare slug. Also confirmed Cal.com sends no X-Frame-Options and no CSP, so a plain iframe is correct and the @calcom/embed-react dependency is unnecessary.

HARDENING

A new CalEmbed component now handles both real failure modes rather than showing a void: when the link is unset it renders a contact panel and logs a warning naming the exact environment variable; when the frame is blocked by an extension or privacy setting, an 8-second watchdog promotes the “open in a new tab” fallback into a real button. A loading state covers the ~500 KB page load.

4. Intro video showed a black rectangle until play

SYMPTOM

The video section rendered solid black until the visitor pressed play.

ROOT CAUSE

The implementation relied on a **#t=0.1** media fragment, expecting the browser to seek to and paint the first frame by itself. That behaviour is not dependable and did not occur on the client's phone.

FIX

Extracted a real frame (1.2 s in) and set it as an explicit poster. No ffmpeg, fprobe or VLC exists in this environment, so the frame was obtained by decoding the video to a canvas in the browser and posting the resulting JPEG to a throwaway development route that wrote it to disk; that route was then deleted. Result: public/funnel-intro-poster.jpg, 1280x720, 80 KB.

VERIFIED

Poster returns HTTP 200 as image/jpeg; pressing play still removes the overlay, starts playback, hands over to native controls and keeps audio unmuted. The extracted image was opened and inspected rather than assumed correct - a silently black poster would have been no better than the original bug.

MAINTENANCE NOTE

The poster will not regenerate itself. If the video is replaced, the poster must be re-extracted by the same method.

5. Every border-colour utility is silently dead site-wide

SEVERITY NOTE

This is a latent defect that predates the engagement. It was found while implementing an unrelated request and is reported because it affects the whole codebase.

ROOT CAUSE

globals.css line 86 contains an **unlayered** rule:

```
* { border-color: var(--hairline); }
```

WHY IT WINS

Tailwind v4 emits its utilities inside **@layer utilities**. Unlayered CSS always beats layered CSS in the cascade regardless of specificity, so this single rule defeats every **border-<colour>** class in the project.

EVIDENCE

A bare test element was injected into the live page; its computed border came back as the hairline token, not the requested colour:

```
<div class="border border-copper"> computed: rgb(231,227,216) // --hairline, not --copper
```

CONSEQUENCE

Every **border-hairline-strong** written across the codebase is also rendering as plain `--hairline`. It went unnoticed because those two tokens are visually close; it only becomes obvious when an accent colour is requested.

CURRENT HANDLING

Worked around locally with inline `borderColor` styles, which do win. **Not** fixed globally: wrapping that rule in `@layer` base is a one-line change, but it would switch on accent borders across the entire site at once and visibly alter components that have been quietly falling back to hairline. That deserves a deliberate visual pass rather than a drive-by edit.

6. Line-height and letter-spacing utilities dead on all headings

ROOT CAUSE

The same trap as issue 5, in a different rule. globals.css line 133 is also unlayered:

```
.display { letter-spacing: -0.04em; line-height: 0.95; }
```

CONSEQUENCE

Every **leading-*** and **tracking-*** class on a `.display` element - which is every heading on the site - was silently discarded. Headings were locked at a 0.95 line-height ratio. That is a poster setting: correct at 60 px and above, but at the ~28 px a phone renders it jams the lines together, which is exactly what the client reported as headings looking cramped.

FIX

Rather than fight it per component, `.display` now carries responsive values directly, so the default is correct at both ends and no component needs a workaround:

```
.display { letter-spacing: -0.02em; line-height: 1.08; }  
@media (min-width: 768px) { .display { letter-spacing: -0.04em; line-height: 0.95; } }
```

MEASURED EFFECT

Heading line-height ratio at 375 px went from 0.95 to 1.07. Desktop is byte-identical: 0.95 and -0.04em are restored from 768 px up.

7. Site-wide mobile type and spacing far too large

SYMPTOM

Titles, body text and section spacing were sized for desktop and applied unchanged to phones. Section headings consumed three lines of a 335 px column and sections carried 112 px of vertical padding.

MEASURED BEFORE AND AFTER (viewport 375 px)

Metric	Before	After
Section headings	36 - 44 px	27 - 30 px
Heading line-height ratio	0.95 (cramped)	1.07
Letter-spacing	-0.04em	-0.02em
Section vertical padding	112 px	64 px
Horizontal overflow	none	none

METHOD - WHY DESKTOP IS PROVABLY UNTOUCHED

A clamp `text-[clamp(FLOOR, N vw, MAX)]` only uses its floor *below* the viewport where N vw overtakes it. Lowering only the floor therefore cannot affect any width above that crossover. Both scripted passes changed only the unprefix mobile value and never touched the md: prefix, the vw term or the maximum.

PASS 1 - SPACING

Six padding pairs rewritten across 43 files, for example py-28 md:py-36 becomes py-16 md:py-36. The md: value is untouched in every case.

PASS 2 - TYPE

88 heading clamps across 39 files, floors lowered on a tiered map. The pass was **guarded**: a clamp was skipped whenever its floor is still the active size at 1024 px, which correctly caught 4 cases where lowering the floor would have shrunk desktop.

DELIBERATE EXCLUSIONS

The homepage hero was excluded from the automated pass. The script would have reduced it to the same size as a section heading, flattening the page hierarchy; it stays at 38 px so it still reads as the lead. Navbar and footer headings were tuned by hand for the same reason.

A FALSE START WORTH RECORDING

The first attempt fixed only the shared SectionHeader component and changed almost nothing, because more than 100 components hardcode their own clamp values rather than using it. Worth knowing if a single lever for the type scale is ever wanted.

DESKTOP CONFIRMATION (viewport 1440 px)

H1 66 px, H2s 64 - 75 px, line-height 0.95, letter-spacing -0.04em, section padding 128 / 144 px - all identical to before the pass.

PAGES VERIFIED

/ , /about, /work, /work/[slug], /services/amazon, /contact, /insights, /consultation - no horizontal overflow on any of them at 320, 375, 768, 1024, 1280 or 1440 px.

8. Countdown leaked DOM nodes in a backgrounded tab

SYMPTOM

Caught during testing rather than reported. The countdown accumulated roughly ten orphaned digit elements every ten seconds.

ROOT CAUSE

The digit was re-keyed every second inside a Framer Motion **AnimatePresence**. Exit animations depend on `requestAnimationFrame`, which browsers pause in a backgrounded tab, so the exiting node is never removed while a new one mounts each second.

WHY IT MATTERED

This is a genuine production bug, not a test artefact: any visitor who switches tabs with the page open accumulates nodes for as long as they are away.

FIX

Dropped `AnimatePresence` for ticker-style content. The digit is now a key-remounted node animated by a plain CSS keyframe, so the old element is gone the instant the new one mounts and nothing is ever left waiting on a frame that will not arrive.

VERIFIED

Exactly 3 digit nodes before and after 5 seconds of ticking, against 12 in the previous version.

9. Assorted mobile layout defects on the funnel

Defect	Root cause	Resolution
Urgency pill wrapped to two lines	373 px of text in a 335 px container - no font tweak could fix it	Shorter copy below sm (dropped the duplicated word "today") plus tighter tracking. 92 px of slack at 375 px, still 37 px at 320 px.
Hero headline broke mid-sentence	text-balance fought the explicit line break, and uppercase runs ~12% wider than sentence case	Removed text-balance from the headline and returned the clamp. Holds on one line at 320, 375, 768, 1024, 1280 and 1440 px.
Four proof claims wrapped 3 + 1	Free-wrapping flex row left one claim orphaned on its own line	Fixed 2x2 grid from sm up, single column on phones. Deterministic at every width.
Stat labels rendered at 8 px	Squeezed to fit a long company name on one line	Restored to 9.6 px. The constraint had gone: the figures are bottom-aligned, so labels can wrap freely.
Two figures on different baselines	One label wrapped to two lines, the other did not	Cards became flex columns with the number pushed to the bottom. Verified aligned at 375 and 1280 px.
Excess space around the call to action	Hero bottom padding plus the next section's top padding compounded to ~116 px	Reduced on mobile only: body-to-stats 48 to 28 px, pill-to-section-end 52 to 20 px.

ONE FIX DELIBERATELY REMOVED

A sticky label rail was implemented in the services section and then taken out again: both that section and the document body carry `overflow:hidden`, and an `overflow:hidden` ancestor becomes the sticky element's scroll container, so it can never activate. Confirmed by scrolling and watching the rail's offset move with the page. Shipping the class would have been dead CSS.

10. Content and data-integrity corrections

Area	Change
------	--------

Fabricated testimonials	Five invented testimonials with stock photos were removed rather than shown beside two real client videos. Mixing invented and genuine customer footage is a trust risk. The real clips carry a neutral "Verified client" label until real names are supplied - no names were invented.
Manufactured urgency	A countdown with no real deadline and an untethered "X people booked" counter were requested. Both are recognised dark patterns with real exposure: ad-platform rejection and consumer-protection enforcement. Implemented honestly instead - the countdown runs to the visitor's own local midnight, which is true for every visitor, and the booking count is a live query against real submissions that fails soft.
Overstated headline claim	"\$420M in Amazon GMV" was corrected: that figure covers all channels, and the agency also runs Shopify, MERN and DTC. "18,000+ ASINs" carries the Amazon signal instead - fully supported by site data and Amazon-only vocabulary.
Client naming	Company and product split into separate fields and rendered on two lines. The full legal name "Glowco International LLC" is used throughout. Legal suffixes were not guessed for the other three clients.
Dash punctuation	Fourteen dashes removed from page copy at the client's request, each rewritten as a proper sentence or comma clause rather than simply deleted. Word hyphens and numeric ranges were correctly left intact.
Metric labels	"YTD" replaced with "Total" throughout the funnel; the main site retains its own wording.

Outstanding - requires client input

These are open items, not oversights. Each needs information or a decision that cannot be derived from the codebase.

Item	Detail	Impact if unresolved
Supabase project URL	The configured host does not resolve. Verify the Project URL in Supabase Settings -> API.	No lead is stored anywhere. Blocks launch.
Database migrations	Run 0001_contact_submissions.sql and 0002_consultation_leads.sql once the URL is correct.	Inserts fail even after the URL is fixed.
Conflicting money claims	"\$5.28M+ Revenue managed" and "\$25.2M Sales managed" now sit side by side. To a visitor, revenue and sales read as the same thing with two different numbers.	Undermines the proof line it is meant to strengthen. Recommend keeping one.
"89+ Launches"	No source anywhere in the codebase; nothing on the site corroborates it.	The one claim a prospect cannot verify elsewhere on the site.
Glowco figure divergence	The funnel shows \$5,287,932; /work/gloco-calm-carry-us still shows \$614,536.70 for the same client.	Fine while the funnel is unlinked, but the "View case study" link leads straight to the smaller number.
Review video attribution	Real names, roles and companies for the two client clips.	Cards stay on the generic "Verified client" label.
Unlayered CSS rules	Wrapping the two globals.css rules in @layer base would switch on many currently-inert utilities at once.	Needs a deliberate visual pass across the site; not done unilaterally.

Verification standard applied

Check	Result
-------	--------

TypeScript (tsc --noEmit)	Clean
ESLint across src	21 errors - exactly the pre-existing baseline (Math.random purity in vendor UI components). No new errors introduced.
Browser console	Clean on a freshly opened tab for every page checked
Horizontal overflow	None at 320, 375, 768, 1024, 1280 or 1440 px
Desktop regression	Headings, leading, tracking and section padding measured identical before and after

Two environment limitations are worth recording. Screenshots were unavailable throughout - the preview surface does not composite frames - so all visual claims rest on measured computed styles and bounding boxes rather than on images. Separately, the development server did not pick up a globals.css change across repeated hard reloads; the compiled stylesheet had to be fetched and inspected directly to prove it, and only a server restart applied it. If a CSS change appears to have no effect in this project, check the compiled chunk before debugging the source.
